Appraisal of penaeid prawn fishery by large mechanized trawlers (Sona boats) off Visakhapatnam, SE coast of India

N Rajendra Naik, G Maheswarudu, J Jayasankar, JB Varma, K Gouri Sankara Rao and T Nageswara Rao

Abstract

Surge in fishing effort and penaeid prawn catch was recorded during the study period with that of 2006-10. Decline in Catch per Hour (CPH) and penaeid prawn ratio (%) to total fish catch was observed. Penaeid prawns accounted for 15.5% of the sona boat landings. Annually, mean penaeid prawn landings were estimated at 6,184 t. Prawn catch excelled by *M. monoceros* (20.5%), *S. crassicornis* (13.7%) and *M. barbata* (7.8%).

Keywords: Large trawler, sona boat, penaeid prawn, Visakhapatnam

Introduction

Trawlers constitutes utmost to total marine fish landings in India. Before introduction of trawlers, indigenous crafts and gears were in operation for harvest. British steam trawler premier operated for the first time off Bombay coast in 1900^[1]. Small mechanised trawlers were introduced by Indo-Norwegian project along east coast for bottom trawling^[2-5]. Trends in landings of commercial trawlers were reported during 1967-74^[6]. In 1985, mini trawlers were introduced and operated along Visakhapatnam coast^[7, 8].

In 1987, sona boats were introduced for voyage fishing in east coast of India. Sona boats are larger in size and worthy to cover distant areas of sea^[9]. Voyage fishing was carried out in the months of October to March during 1987 to 1990^[10]. Sona boats (large trawlers) (13-15m OAL) are capable for fishing up to depth range of 100 m. Large trawlers with 20 mm mesh size (cod end), 5 m height mouth opening, 102 hp engine capacity were engaged for fishing. Study conducted to appraise penaeid prawn fishery by large (sona boats) mechanized trawlers.

Materials and Methods

Multi stage random sampling method of ICAR- CMFRI was followed to collect data on fish catch and fishing effort by large (sona boats) trawlers off Visakhapatnam coast from 2011 to 2015^[11]. Sampling was carried out once in a week to estimate catch and species composition. Data was collected on fish catch, fishing effort and CPH (Catch per Hour) through direct observation and enquiry. Total fish catch was estimated based on the total fishing days of the month. Status of exploitation and expected penaeid prawn landings (t) were estimated by Schaefer production model (CEDA) based on fishing effort and penaeid prawn landings by large trawlers^[12].

Results and Discussion

Visakhapatnam is one of the major fishing harbours in east coast of India. Mechanized trawlers play vital role in penaeid prawn harvest. Large trawlers (sona boats) comprises significantly to total trawl catch. Study conducted to assess penaeid prawn fishery by large (sona boats) mechanized trawlers from 2011 to 2015. Sona boats operated throughout the year except during the fishing ban period. Surge in fishing effort, penaeid prawn catch and fish catch was recorded during the study period with that of 2006-10. Decline in Catch per Hour (CPH) and penaeid prawn proportion (%) to total fish catch was observed.

Annually, about 8,979 units of sona boats were under operation from Visakhapatnam fishing harbor with the mean fishing effort at 15.1 lakh h (Table 1) during the study period. Due to involvement of sona boats in multiday fishing, fishing effort per trip was varied from 152.3 h

To 218.8 h with the mean at 172.7h. Maheswarudu *et al.*, 2018 reported about 7,575 units with an average at 10.2 lakh h of fishing ^[13]. Rao *et al.*, 1988 reported similar trend in fishing effort ^[6].

After successful completion of multiday fishing trip, sona boats lands fish catch at Visakhapatnam fishing harbor. Annually, mean penaeid prawn landings were estimated at 6,184 t. Penaeid prawn landings depends on abundance, because of that monthly landings varied from 141 (April) to 887 t (Aug.) (Table 2). Prawn landings by trawlers increased from 132 t (1967) to 6,191 t (1977) and declined to 2,026 t in 1978 ^[7]. Maheswarudu *et al.*, 2018 reported 4,601 t annual catch of penaeid prawns ^[13].

Because of divergence in landings, mean penaeid prawn catch per hour (CPH) was estimated at 4.25 kgh⁻¹ with the peak in January (5.49 kgh⁻¹). Sastry and Chandrasekhar, 1986 reported annual CPH for prawns as 3 kg and 2.7 kg for the period 1982-83 and 1983-84 respectively ^[14]. Rao *et al.*, 1988 reported that CPH indicated abundance of prawns in four phases ^[6]. Maheswarudu *et al.*, 2018 reported CPH of penaeid prawn at 4.53 kg h⁻¹ ^[13].

Due to diversity in the catch, pinnacle of penaeid prawn composition (20.3%) was estimated in the month of June with the mean at 15.5%. Rajkumar, 2004 also reported 11.9% prawns to total marine fish landings ^[10]. Prawns formed 16.7% and 30.2% of total trawl catch in 1968 and 1972 respectively ^[6]. Penaeid prawns accounted for 9.8% and 15.9% of the total marine fish catch respectively ^[13, 15].

Alltogether, seven groups (generas) of penaeid prawns comprised to the total catch with the paramount of

Metapenaeus sp. (34.65%) and *Solenocera* sp. (18.4%) (Fig.1). Out of the 22 species, prawn catch exceeded by *Metapenaeus monoceros* (20.5%), *Solenocera crassicornis* (13.7%) and *M. barbata* (7.8%) (Fig. 2).

Muthu, 1968 observed 37 species of penaeid shrimps from the commercial catch at Visakhapatnam and Kakinada ^[8]. Maheswarudu *et al.*, 2014 reported 19 species of penaeid prawns along Andhra coast ^[15]. Maheswarudu *et al.*, 2018 reported 24 species of penaeids and the catch was dominated by *M. Monoceros* (1813 t) ^[13].

In general, surge in fishing effort and penaeid prawn catch was recorded during the study period with that of 2006-10. Decline in Catch per Hour (CPH) and penaeid prawn proportion (%) to total fish catch was observed. Overall, rise in catch was estimated for *Trachypenaeus* sp. (604.3%) followed by *P. japonicus* (149.1%), *P. semisulcatus* (101%), *Metapenaeopsis* sp. (79.6%) *P. monodon* (60.4%), *Parapenaeopsis* sp. (56.6%). *M. affinis* (52.3%), *P. indicus* (37.1%) and *Solenocera* spp. (21.8%). Decline in catch and CPH (kgh⁻¹) was observed for *P. merguensis*, *M. Monoceros*, *M. dobsoni* and *Parapenaeus* spp. (Table 3).

Expected penaeid prawn landings (t) were estimated by Schaefer production model (CEDA) based on fishing effort and penaeid prawn catch for the period 2006 to 2015. Figure 3 illustrates the present status of penaeid prawn landings and expected penaeid prawn landings. The r² value for fishing effort and penaeid prawn catch was 0.6. Out of the ten years period (2006 to 2015), penaeid prawns were under exploited in the year 2013 and over exploited in 2008, 2010 and 2014.

Note: Species-wise mean values for the period 2011 to 2015 and 2006 to 2010 are given in the table

Fig 1: Group-wise mean proportion (%) of penaeid prawns landed by large trawlers from 2011 to 2015

Fig 2: Species composition (%) of penaeid prawns landed by large (sona boats) trawlers

Fig 3: Expected (thin line) catch (t) and observed catch (t) of penaeid prawns from 2006 to 2015

Conclusion

Study revealed that, surge in fishing effort and penaeid prawn catch was recorded during the study period with that of 2006-10. Decline in Catch per Hour (CPH) and penaeid prawn proportion (%) to total fish catch was observed. Penaeid prawns accounted for 15.5% of the sona boat landings. Annually, mean penaeid prawn landings were estimated at 6,184 t. Mean penaeid prawn catch per hour (CPH) was estimated at 4.25 kg^h⁻¹. Penaeid prawns were over exploited in 2008, 2010 & 2014 with that of expected catch. As a whole, sona boats constantly harvesting penaeid prawns in sustainable manner and it is advised to confine fishing effort at current altitude of operation.
